SUBJECT: **Draft Final Report: CIAR Study of Personal ETS Expsoure in the UK**

Attached for your information and review is the draft final report of the CIAR-sponsored study of personal ETS exposure conducted by Hazleton in the UK. If you have questions, comments, points that require clarification, etc., please communicate them to me no later than 15 July. There is still time to ask Hazleton to make minor changes.

Part of the contract between CIAR and Hazleton requires them to provide a manuscript of a paper based on this work which they will submit for publication in a technical journal. The preparation of that manuscript is ongoing and may well be aided by any suggestions you can provide.

This study is the prototype for the larger US study currently underway. The basic methods used and the analytes measured in the US study are the same as those reported here. The major difference is that the US study is designed to provide a separate measure of workplace exposure; i.e., there will be two samplers used by each participant in a 24-hour period: one for workplace exposure and the second for "all other" exposure.
